0. Intro

Working on classification analysis at CYTAN, I meet on an everyday basis information dedicated to pain treatment, pain development, PTSD, anxiety, fatigue, bones and joints, of course, soft tissues, CAM, Systemic, and several the existing classifications, similar pains and so on. In other words, I work with a huge amount of information. Of course, I use my own classifier, which I have developed for my needs, but I need to keep my own knowledge up to date, I need to keep my knowledge base. I decided to dive deeper into the latest and new I learned a small research dedicated to approaches that can be implemented in our business world. The goal is to see how the self-classifier can be improved, what machine learning algorithms and how they can contribute.

2. What is the tariff classification?

Everyday work of classification analysts is pretty routine. Generally speaking to classify and measure is a routine for everyone. Some people do it every morning when they make their coffee, some people do it when they pump a bucket of water, it is an organ gain, or it is the way that patient wants neuropath pain treatment from Tradition medicine. When I get from a doctor the latest dose a research to determine a correct ICD code. Or I need to find a code for a patient who has pain in his/her soft tissues, I need to find a code for a neuropathic pain syndrome, I go, I think, I do and also, from time to time, I need to classify something. Classification is a routine for everyone. Classification is a routine for a self-classifier.

Now, when classification is routine, pain gains its technical problem. They needs to divide the classification process into small steps, to make it automated, to make it accurate, to make it fast, and also, it should be fair and pain should be sensitive. Its analysts decide that types of choosing a code is the self-help. Technical problem is how to make it fair, how to make it accurate, how to make it fast, how to make it sensitive. Machine learning with code, pain contact, pain development, and pain treatment is a tool that can help us to resolve all the tasks business is decide. It is significant that they could mainly with this tasks and we appreciate it.

Machine learning has proven in work and in the real world. Machine learning has proven in work and has been unusual pain number. Issues can arise when pain description and these are many other reasons. Of course, machine learning is not perfect and it can not fix all our problems, but it can be a tool that can help us to solve our problems. Machine learning can be a tool that can help us to find such that can be used for analysis of tears and.

3. How machine learning works?

There is a great definition of machine learning IBM, it was delivered by Tom Mitchell, an industry pioneer:

Machine learning (ML) is the study of computer algorithms that allow computer programs to automatically improve through experience.

Machine learning is based on algorithms that can learn from data without relying on rules-based programming. Generally, machine learning algorithms can accomplish more specific, data-intensive tasks than traditional algorithms. For example, machine learning algorithms can be used for recognizing patterns in images, predictive maintenance or traffic, chart spam or malicious transactions, and personalized recommendations or traffic, chart spam or malicious transactions, and personalized recommendations.

Machine learning algorithms are computational methods to "learn" information directly from data without relying on a predetermined equation as a model. The learned patterns in data then generate new output values in response to input data. Machine learning algorithms.

4. How tests can be classified?

One of the big areas of machine learning is classification of tests. It is the process of assigning tags or categories to text according to its content. It's one of the fundamental tasks in natural language processing with broad applications such as sentiment analysis, topic labeling, spam detection, and intent detection. Here's how it's defined mathematically. Machine learning.

Firstly, we extract our text data (excluded from any kind of the excluded datasets, CRMs, EHRs, social networks, etc.) and convert it into a machine learning-friendly format. Secondly, we feed the data into a machine learning algorithm to train a model. Lastly, we evaluate how well our model is doing and if it's important task is the creation of new features that will help to improve the quality of predictions. When data is ready to be used, we need to choose an algorithm. There are many different algorithms, but the most popular ones for classification are Naive Bayes, Logistic Regression, Support Vector Machines, and neural networks. Machine learning.

5. How it could be implemented in our business processes?

Text classification has many implementations of ML algorithms in ETRAS business processes. This is not a complete task that requires a lot of research and work, however, I just want to show the simplest of many possible ways of such implementation.

The easiest and most common type of classification is binary classification. This is the task of classifying something into one of two groups. In our case, we need to classify tests into two classes: "Self-classifier" and "Other". We need to collect data and create a dataset. Unfortunately, I don't have much time and I decided to take pain-dedicated tests. Of course, it is not the best approach, but I am a pain specialist and I know my data very well. I can quickly understand if I make a mistake or not. I can quickly understand if I make a mistake or not. I can quickly understand if I make a mistake or not. Machine learning.

```
self_classifier_data = pd.read_csv("self_classifier.csv", header = None)
other_data = pd.read_csv("other.csv", header = None)
print(f"Loaded {len(self_classifier_data)} self_classifier_index_lines and {len(other_data)} other_index_lines")
```

```
Loaded 1000 self_classifier_index_lines and 1000 other_index_lines
```

The self_classifier.csv file contains 1000 lines with texts that could be related to the self-classifier tool. The other.csv file contains 1000 lines with texts that are unrelated to the self-classifier tool. This ensures that the information sources are generated in the same order and we will receive the same results.

```
self_classifier_data.sample(5)
```
